Sibling Resolution

New Problem We Term "Sibling Resolution:"

Given a candidate (*IPv*4, *IPv*6) address pair, determine if these addresses are assigned to the same cluster, device, or interface.

- Sibling resolution may be either active or passive.
- Lots of prior work on passive sibling associations: e.g. web-bugs, javascript, etc.
- Prior work focuses on clients (adoption, performance)
- This work:
 - Targeted, active test: on-demand for any given pair
 - Infrastructure: finding server siblings

イロト イ理ト イヨト イヨト

Motivation

Why?

- IPv4 and IPv6 expected to co-exist (for a long while?) \rightarrow dual-stacked devices
 - Track adoption (and dis-adoption)
 - Track IPv6 evolution
- Security:
 - Inter-dependence of IPv6 on IPv4 (and vice-versa)
 - e.g. attack on IPv6 resource affecting IPv4 service
- Performance:
 - Measurements of IPv4 vs. IPv6 performance
 - Desire to isolate path vs. host performance
 - Correlating geolocation, reputation, etc with IPv4 host counterpart.

Methodology

Targeted, Active Technique

Targeted, Active Technique

- Intuition: IPv4 and IPv6 share a common transport-layer (TCP) stack
- Leverage prior work on physical device fingerprinting using TCP timestamp clockskew [Kohno 2005]
- TCP timestamp option: "TCP Extensions for High Performance" [RFC1323, May 1992]
- Universal support for TCP timestamps (modulo middleboxes, proxies). Enabled by default.

Methodology

TCP Timestamp Clock Skew

TCP Timestamp Clock Skew

- TS value: 4 bytes containing current clock
- Note: RFC does not specify value of TS (assume millisec for now)
- Note: TS clock \neq system clock
- Note: TS clock frequently unaffected by system clock adjustments (e.g. NTP)
- **Basic Idea:** Probe over time. Fingerprint is clock *skew* (and remote clock resolution).

Methodology

TCP Timestamp Clock Skew

Some Details

- Must be able to connect to remote TCP service on each host
- Periodically connect to TCP service.
- Given a sequence of timestamp offsets, use linear programming to obtain a line that minimizes distance to points, constrained to be under data points.
- Obtain: $y_4 = \alpha_4 x + \beta_4$ and $y_6 = \alpha_6 x + \beta_6$
- Angle between lines then:

$$\theta(\alpha_4, \alpha_6) = \tan^{-1} \left| \frac{\alpha_4 - \alpha_6}{1 + \alpha_4 \alpha_6} \right|$$

• Siblings if: $\theta < \tau$

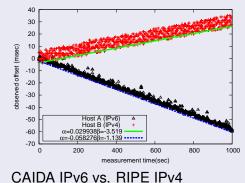

Example

Example

- Gather 4 timestamp series:
 - www.caida.org (v4 and v6)
 - www.ripe.net (v4 and v6)

Example

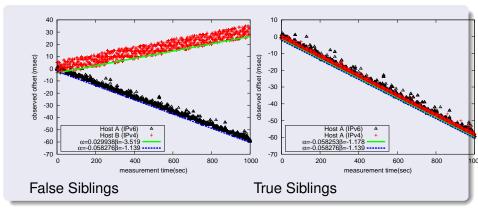

- Observe different skew slopes (one negative)
- Different timestamp granularity
- y = 0.029938x equates to skew of ≈ 1.8ms / minute, or ≈ 15 minutes per year.

False siblings!

Example

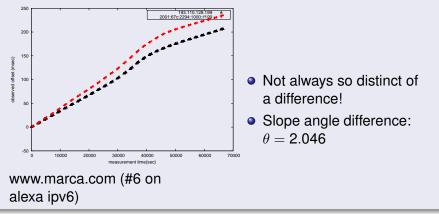

- CAIDA IPv4 vs. CAIDA IPv6: identical slopes ($\theta = 0.0098$)
- CAIDA IPv6 vs. RIPE IPv4: different slopes ($\theta = 31.947$)

Machine Sibling Inference

Machine Sibling Inference Methodology:

- Analyze Alexa top 100,000 websites
- Pull A and AAAA records
- 1398 (\approx 1.4%) have IPv6 DNS
- Repeatedly fetch root HTML page via IPv4 and IPv6 via deterministic IP address
- Record all packets

・ 同 ト ・ ヨ ト ・ ヨ

Machine Sibling Inference

Alexa 100K Targeted Machine-Sibling Inference

Case	Count
v4 and v6 non-monotonic (possible siblings)	109 (7.8%)
v4 or v6 non-monotonic (non-siblings)	140 (10.0%)
v4 and v6 no timestamps (possible siblings)	94 (6.7%)
v4 or v6 no timestamps (non-sibling)	101 (7.2%)

- Our technique fails when timestamps are not monotonic across TCP flows (e.g. load-balancer or BSD OS)
- Or, when timestamps are not supported (e.g. middlebox)
- Note, can disambiguate non-siblings

Machine Sibling Inference

Alexa 100K Targeted Machine-Sibling Inference

Case	Count
v4 and v6 non-monotonic (possible siblings)	109 (7.8%)
v4 or v6 non-monotonic (non-siblings)	140 (10.0%)
v4 and v6 no timestamps (possible siblings)	94 (6.7%)
v4 or v6 no timestamps (non-sibling)	101 (7.2%)
Skew-based siblings	839 (60.0%)
Skew-based non-siblings	115 (8.3%)
Total	1398 (100%)

• 25.5% (356) non-siblings

• 43% of skew-based non-siblings are in different ASes

DNS Machine Siblings

DNS Machine Siblings

- With respect to collecting DNS siblings, would like to differentiate between *machine* and *equipment* siblings.
- Tie passive and active DNS collection with skew-based inference.
- For addresses with an DNS equivalence class:
 - Add IP to machine sibling group with small $\theta < 1.0$
 - Else $\theta \ge 1.0$, create new sibling group with single IP.
 - Until all IPs of equipment equivalence class clustered

Relationship between equipment siblings and machine siblings.

Evaluating Sibling Inference Accuracy

Evaluating Inference Accuracy

- Seek to understand the accuracy of timestamp-based sibling inference
- Use ground-truth dual-stacked Akamai machines
- No load-balancers or middleboxes
- Experiment: 100 known-siblings, 100 known non-siblings (random v4/v6 pairs drawn from Akamai population)
- Hardest scenario: single organization, similar boxes, same operating system, etc.

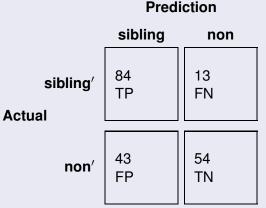

22/24

(I) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1))

NPS-SIX 2013

Evaluating Sibling Inference Accuracy

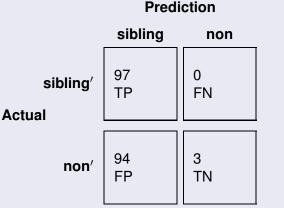

Evaluating Inference Accuracy

- Threshold $\tau = 0.002$ gives best results!
- 71% accuracy, 66% precision, 87% recall (f-score: 0.75)

Evaluating Sibling Inference Accuracy

Evaluating Inference Accuracy

• No false negatives w/ $\tau = 0.05$ (but more FP's)

• 52% accuracy, 51% precision, 100% recall (f-score: 0.67)

Current Work

Current Work

- Quantify whether vantage point imparts any difference on results
- Refine inference algorithm to deal with load-balancers
- Refine algorithm to produce better accuracy, eliminate false positives
